

Shortest Paths and DP

DP: Telescope Scheduling

```
for (i=1 to n) do:  
    M[i] = max{b_i + M[p(i), M[i-1]]}
```

Note $p(i)$: index ($< i$)

Thus the network flow would simply be a linked list of 0's with occasional arcs from $p(i)$ to i with a cost of $-b_i$

Coin Game:

$$M[i,j] = \max\{\min\{M[i+1,j-1], M[i+2,j]\}, \min\{M[\dots]\}\}$$
